

ABSTRACT OF THE DISCLOSURE

A mobile communication system comprises a detecting unit to detect information concerning a moving speed of a mobile terminal, and a selection
5 controlling unit to select a use frequency in a higher frequency band when the speed information detected by the detecting unit is a higher speed, while selecting the use frequency in a lower frequency band when the
10 detected information is a lower speed, and assigning it to the mobile terminal. In a mobile communication system in which a relationship between a terminal moving speed (Doppler frequency) and transmission quality degradation is non-monotonous, the
15 communication quality can be improved and the channel capacity can be increased.
